### 4.1 Interval Scheduling

## Interval Scheduling

Interval scheduling.

- Job $j$ starts at $s_{j}$ and finishes at $f_{j}$.
- Two jobs compatible if they don' $\dagger$ overlap.
- Goal: find maximum subset of mutually compatible jobs.

## Interval Scheduling: Greedy Algorithms

Greedy template. Consider jobs in some order. Take each job provided it's compatible with the ones already taken.

- [Earliest start time] Consider jobs in ascending order of start time $s_{j}$.
- [Earliest finish time] Consider jobs in ascending order of finish time $f_{j}$.
- [Shortest interval] Consider jobs in ascending order of interval length $f_{j}-s_{j}$.
- [Fewest conflicts] For each job, count the number of conflicting jobs $c_{j}$. Schedule in ascending order of conflicts $c_{j}$.

## Interval Scheduling: Greedy Algorithms

Greedy template. Consider jobs in some order. Take each job provided it's compatible with the ones already taken.
breaks earliest start time
breaks shortest interval
breaks fewest conflicts

## Interval Scheduling: Greedy Algorithm

Greedy algorithm. Consider jobs in increasing order of finish time.
Take each job provided it's compatible with the ones already taken.

```
Sort jobs by finish times so that f}\mp@subsup{f}{1}{}\leq\mp@subsup{f}{2}{}\leq\ldots\leq\mp@subsup{f}{n}{}
    , jobs selected
A}\leftarrow
for j = 1 to n {
    if (job j compatible with A)
        A}\leftarrowA\cup{\mp@code{{}
}
return A
```

Implementation. $O(n \log n$ ).

- Remember job $j^{*}$ that was added last to $A$.
- Job $j$ is compatible with $A$ if $s_{j} \geq f_{j *}$.

## Interval Scheduling: Analysis

Theorem. Greedy algorithm is optimal.

## Pf. (by contradiction)

- Assume greedy is not optimal, and let's see what happens.
- Let $i_{1}, i_{2}, \ldots . i_{k}$ denote set of jobs selected by greedy.
- Let $j_{1}, j_{2}, \ldots j_{m}$ denote set of jobs in the optimal solution with $i_{1}=j_{1}, i_{2}=j_{2}, \ldots, i_{r}=j_{r}$ for the largest possible value of $r$.

## Interval Scheduling: Analysis

Theorem. Greedy algorithm is optimal.

## Pf. (by contradiction)

- Assume greedy is not optimal, and let's see what happens.
- Let $i_{1}, i_{2}, \ldots . i_{k}$ denote set of jobs selected by greedy.
- Let $j_{1}, j_{2}, \ldots j_{m}$ denote set of jobs in the optimal solution with $i_{1}=j_{1}, i_{2}=j_{2}, \ldots, i_{r}=j_{r}$ for the largest possible value of $r$.

### 4.2 Interval Partitioning

## Interval Partitioning

Interval partitioning.

- Lecture $j$ starts at $s_{j}$ and finishes at $f_{j}$.
- Goal: find minimum number of classrooms to schedule all lectures so that no two occur at the same time in the same room.

Ex: This schedule uses 4 classrooms to schedule 10 lectures.

## Interval Partitioning

Interval partitioning.

- Lecture $j$ starts at $s_{j}$ and finishes at $f_{j}$.
- Goal: find minimum number of classrooms to schedule all lectures so that no two occur at the same time in the same room.

Ex: This schedule uses only 3 .

## Interval Partitioning: Lower Bound on Optimal Solution

Def. The depth of a set of open intervals is the maximum number that contain any given time.

Key observation. Number of classrooms needed $\geq$ depth.
Ex: Depth of schedule below $=3 \Rightarrow$ schedule below is optimal.
$a, b, c$ all contain 9:30
Q. Does there always exist a schedule equal to depth of intervals?

## Interval Partitioning: Greedy Algorithm

Greedy algorithm. Consider lectures in increasing order of start time: assign lecture to any compatible classroom.

```
Sort intervals by starting time so that s}\mp@subsup{s}{1}{}\leq\mp@subsup{s}{2}{}\leq\ldots\leq\mp@subsup{s}{n}{}
d }\leftarrow0\longleftarrow\mathrm{ number of allocated classrooms
for j = 1 to n {
    if (lecture j is compatible with some classroom k)
    schedule lecture j in classroom k
    else
        allocate a new classroom d + 1
        schedule lecture j in classroom d + 1
        d}\leftarrowd+
}
```

Implementation. $O(n \log n)$.

- For each classroom k, maintain the finish time of the last job added.
- Keep the classrooms in a priority queue.

## Interval Partitioning: Greedy Analysis

Observation. Greedy algorithm never schedules two incompatible lectures in the same classroom.

Theorem. Greedy algorithm is optimal.
Pf.

- Let $d=$ number of classrooms that the greedy algorithm allocates.
- Classroom d is opened because we needed to schedule a job, say j, that is incompatible with all d-1 other classrooms.
- Since we sorted by start time, all these incompatibilities are caused by lectures that start no later than $s_{j}$.
- Thus, we have d lectures overlapping at time $\mathrm{s}_{\mathrm{j}}+\varepsilon$.
- Key observation $\Rightarrow$ all schedules use $\geq$ d classrooms. "

### 4.3 Shortest Paths in a Graph

## Shortest Path Problem

Shortest path network.

- Directed graph $G=(V, E)$.
- Source s, destination t.
- Length $\ell_{e}=$ length of edge e.

Shortest path problem: find shortest directed path from s to t.
cost of path = sum of edge costs in path

Cost of path s-2-3-5-t
$=9+23+2+16$ $=48$.

## Dijkstra's Algorithm

Dijkstra's algorithm.

- Maintain a set of explored nodes $S$ for which we have determined the shortest path distance $d(u)$ from $s$ to $u$.
- Initialize $S=\{s\}, d(s)=0$.
- Repeatedly choose unexplored node $v$ which minimizes

$$
\pi(v)=\min _{e=(u, v): u \in S} d(u)+\ell_{e},
$$

add $v$ to $S$, and set $d(v)=\pi(v)$.
shortest path to some $u$ in explored part, followed by a single edge (u, v)

## Dijkstra's Algorithm

Dijkstra's algorithm.

- Maintain a set of explored nodes $S$ for which we have determined the shortest path distance $d(u)$ from $s$ to $u$.
- Initialize $S=\{s\}, d(s)=0$.
- Repeatedly choose unexplored node $v$ which minimizes

$$
\pi(v)=\min _{e=(u, v): u \in S} d(u)+\ell_{e},
$$

add $v$ to $S$, and set $d(v)=\pi(v)$.
shortest path to some $u$ in explored part, followed by a single edge (u, v)

## Dijkstra's Algorithm: Proof of Correctness

Invariant. For each node $\mathrm{u} \in \mathrm{S}, \mathrm{d}(\mathrm{u})$ is the length of the shortest s - u path. Pf. (by induction on $|S|$ )
Base case: $|S|=1$ is trivial.
Inductive hypothesis: Assume true for $|S|=k \geq 1$.

- Let $v$ be next node added to $S$, and let $u-v$ be the chosen edge.
- The shortest $s$-u path plus ( $u, v$ ) is an $s-v$ path of length $\pi(v)$.
- Consider any $s-v$ path $P$. We'll see that it's no shorter than $\pi(v)$.
- Let $x-y$ be the first edge in $P$ that leaves $S$, and let $P^{\prime}$ be the subpath to $x$.
. $P$ is already too long as soon as it leaves $S$.

## Dijkstra's Algorithm: Implementation

For each unexplored node, explicitly maintain $\pi(v)=\min _{e=(u, v): u \in S} d(u)+\ell_{e}$.

- Next node to explore = node with minimum $\pi(v)$.
- When exploring $v$, for each incident edge $e=(v, w)$, update

$$
\pi(w)=\min \left\{\pi(w), \pi(v)+\ell_{e}\right\} .
$$

Efficient implementation. Maintain a priority queue of unexplored nodes, prioritized by $\pi(v)$.

| PQ Operation | Dijkstra | Array | Binary heap | d-way Heap | Fib heap ${ }^{\dagger}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Insert | $n$ | $n$ | $\log n$ | $d \log _{d} n$ | 1 |
| ExtractMin | $n$ | $n$ | $\log n$ | $d \log _{d} n$ | $\log n$ |
| ChangeKey | $m$ | 1 | $\log n$ | $\log _{d} n$ | 1 |
| IsEmpty | $n$ | 1 | 1 | 1 | 1 |
| Total |  | $n^{2}$ | $m \log _{n}$ | $m \log _{m / n} n$ | $m+n \log n$ |
